$\text{Fe}_3\text{GaTe}_2$ , an itinerant van der Waals ferromagnet, has recently been reported to exhibit a Curie temperature ( $T_C$ ) of 380 K [1], exceeding room temperature and higher than that of  $\text{Fe}_3\text{GeTe}_2$  ( $T_C=230$  K [2]).  $\text{Fe}_3\text{GaTe}_2$  is isostructural with  $\text{Fe}_3\text{GeTe}_2$  and has one less valence electron; however, its nearest-neighbor exchange coefficients ( $J_1$  and  $J_2$ ) are smaller, even though its  $T_C$  is higher. Here, we show that higher-order magnetic exchange interactions play a crucial role in the enhanced  $T_C$  of  $\text{Fe}_3\text{GaTe}_2$ , based on first-principles calculations of exchange coefficients. Due to a one-electron difference, higher-order exchange coefficients ( $J_3$  and beyond) are positive in  $\text{Fe}_3\text{GaTe}_2$  but negative in  $\text{Fe}_3\text{GeTe}_2$ , which can be understood in terms of hybridization exchange. In this, crystal-field-split ligand  $p$  orbitals play a key role for long-range ferromagnetism in  $\text{Fe}_3\text{GaTe}_2$  and antiferromagnetism in  $\text{Fe}_3\text{GeTe}_2$ . Unlike super-exchange, hybridization exchange is nonperturbative and intrinsic to covalent bonding, providing a design principle for the search for materials with higher  $T_C$ . As a result,  $\text{Fe}_3\text{GaTe}_2$  exhibits a larger total sum of all possible exchange coefficients. Using these  $J$  values,  $T_C$  of  $\text{Fe}_3\text{GaTe}_2$  and  $\text{Fe}_3\text{GeTe}_2$  is evaluated using both mean-field theory [3] and Monte Carlo simulations [4].
